To study the relationship between quality of life (QOL) and disease course in patients with systemic sclerosis (SSc). Sixty-seven patients with SSc with and without interstitial lung disease were included.

QOL was measured with a self-administered questionnaire. For the whole group, the disease duration was significantly longer in patients with a shorter QOL. Patients who were never or currently smokers had a shorter QOL. The QOL was not significantly correlated with disease duration, age, or extent of skin lesions in patients with interstitial lung disease. The rate of change in Raynaud's phenomenon, the presence of distal ulcers, and of mechanic's hands and fingers were significantly correlated with QOL.
