you need the following program: . The present invention relates to a system for connecting a hydrophone to a sensor system and more particularly to a system for connecting a hydrophone to a head-up display to provide a submerged interface and a user interface for an operator. Hydrophone is a device to determine the location of an object in a body of water by means of an acoustic wave. A hydrophone used in sonar systems for submerged applications, e.g., marine navigation, plays a vital role in steering a ship and thereby in ensuring that the ship operates within safe parameters. A typical underwater navigation system consists of a sonar head and a hydrophone. The sonar head detects echoes that originate from sound waves reflected off of objects such as fish, bottom sediment, and bubbles. As the sonar head detects the reflections, it transmits the detected echoes to the hydrophone, which in turn converts these echoes into an electrical signal. In a typical system a two-way acoustic link, usually a fiber optic cable, connects the sonar head to the hydrophone. However, a fiber optic cable is not ideal for underwater operations because of the limited space in a submarine in which to lay the fiber optic cable, and because of the difficulty in maintaining the alignment of the fiber optic cable. There have been many proposals to employ acoustic power modulation, including pulsed modulated sound waves, which is an advantageous technique for transferring acoustic energy in water. When used in an underwater environment, the hydrophone is typically a transducer that converts the acoustic wave into an electrical signal. In order to make a hydrophone connect to a head-up display, electrical signals are typically converted into an optical signal using a photosensor. The hydrophone and the photosensor are generally integrated within the head-up display to form a sonar head. Some sonar heads also

include a microprocessor and a display. When there is too much noise for proper acoustic detection, it may be beneficial to remove, filter or eliminate a portion of the noise. However, removing this noise is difficult. The conventional methods require the use of a delay period that is long enough for the noise to be removed. The use of such a long delay period, however, is not desired because this can induce a large angular rotation of the sensor and correspondingly disrupt the user's visual system.Palliative and terminal therapy: Patient perspective from a developing country.
