* The Photoshop CS series is a professional, but very expensive, program. * The Photoshop Elements 13 series is a more affordable consumer alternative that has all of Photoshop's features and a simplified interface. * Photoshop can create layered Photoshop images, although Elements doesn't, but Elements does allow you to create a workspace that includes a collection of Photoshop palettes and ladders, as well as other items. These palettes and ladders can be accessed and custom arranged by simply dragging the created items to the workspace. ## Working with Layers Photoshop is designed to enable you to add or subtract layers, change their opacity, and merge them, make them transparent, and perform other actions on them. Layers can be mixed, and combined with other layers, to create a layered Photoshop image. Layers are created automatically when you open an image. Layers appear as stackable boxes on top of each other. When you create a new layer, you can call it anything you like. Here are a few conventions that are used most often: * **Layer 1:** The most recent layer. * **Layer 2:** A layer that you haven't saved. * **Layer 3:** The original image with all the layers for editing built in. When you delete a layer, it's gone and no longer appears in your current project. When you save a file, you typically save the file with a `_.psd_` extension, which enables the software to load the file and load the layers of the file into Photoshop. You'll be working with many layers in this book and have some understanding of the important terminology regarding layers, so I will now explain each layer's role and introduce some terms that you'll likely see.

Demonstration of a sustained multidrug resistance phenotype in leukemic blast cells after withdrawal of fluorodeoxyuridine. P-glycoprotein (P-gp), also known as multidrug resistance protein (MRP), has been identified in many cell types and is associated with a multidrug-resistant phenotype. In this study, the use of several human leukemic cell lines with and without P-gp as a model system is described to demonstrate the generation of a multidrug-resistant phenotype after the removal of fluorouracil, an agent that induces expression of P-gp. Three human leukemic cell lines with and without P-gp (WSU-MP6, WSU-NP6, and WSU-NHT) were treated with 10 microM fluorouracil, 50 microM fluorodeoxyuridine (FdUrd), or 100 microM fluorouracil for 48 hours. The induction of P-gp in these cell lines was confirmed by flow cytometry using two monoclonal antibodies. Drug sensitivity was determined by the MTT assay. Cells treated with FdUrd showed an increased growth inhibition of approximately 5- to 10-fold, which was also reflected in a decrease in the 50% inhibitory concentration (IC50) of the FdUrd. The IC50 of etoposide in all three cell lines with P-gp was reduced from 2.15 to 0.5 microM. Cells treated with 10 microM FdUrd for 48 hours developed a multidrug resistance phenotype when analyzed by flow cytometry. A reduction in the IC50 of FdUrd from 6.2 to 2.1 microM was observed. In contrast, the IC50 of etoposide was only slightly affected in the cell lines with P-gp (0.69 to 0.65 microM) after treatment with FdUrd. Fluorouracil treatment appears to trigger a multidrug resistance phenotype in cell lines with P-gp. The development of P-gp-mediated multidrug resistance may be of particular clinical importance in leukemic cells before or during antineoplastic treatment of children with acute leukemia and in bone marrow specimens from patients during the early phases of leukemia.
